1995 Hawaii Site Response Experiment

Three IRIS PASSCAL seismic instruments (6-channel RefTeks) were deployed at existing USGS strong motion sites in Hawaii (Figure 1), from mid-August to late November 1995. The goal was to obtain weak-motion recordings to use for site response studies. Sensors used were USGS 1 Hz L-4's (3-component). For purposes of converting input voltage to ground motion, the sensitivity of the L-4 is 166.54 v/m/s and it is a critically damped 1 Hz geophone. The instruments were deployed indoors, and were powered by 12-volt car batteries with trickle chargers attached. This report documents the triggered data recorded on the stations.

Data Collection

Data were recorded in triggered mode for all stations. Table 1 presents the station coordinates and Table 2 documents the station installation and removal history. Table 3 contains the parameter settings used for the instruments. A preliminary HVO event list is shown in Table 4 for events above M 2.5.

The data have been assembled in the form of SEG-Y day volumes (Stream 1 for triggered data). Ratefiles (as well as log and error files) are provided for determining clock corrections; they have not been incorporated into the SEG-Y data.

Known Problems

One site (USDA) was down for 17 days at the end of the deployment period due to a filled disk.

Tapes Provided

The data archive includes one tape with miscellaneous information (log and error files, event catalogs and processing scripts) and a set of day-volume tapes (compilation of all triggered data; 2 tapes, about 2 Gbytes).
